Guided Lab: Catalogue Summary Report

Step 8: Explain which result contains dictionaries and which contains one dictionary

The category report (qs) contains several dictionaries. It returns one dictionary for each category (Books and Toys). This happens because values() returns dictionaries, and annotate() adds the calculated fields (product_count, average_price, total_stock) inside each dictionary. So the result is a QuerySet of dictionaries.

The overall summary (overall_summary) contains one dictionary only. It holds the whole summary together: total_products and average_price. This happens because aggregate() collapses all the active products into a single result and returns a plain dict, not a QuerySet.
