Exit ticket: explain why code becomes required only after the data migration.

When I first add the code field, the Product table already contains rows, and none of them has a code yet. If I made the field required (null=False) and unique (unique=True) right away, the migration would fail. The existing rows would have empty values, which a required field does not allow, and Django would have no unique value to give each of them.

To avoid this, I do it in stages. First I add code with null=True so the old rows stay valid. Then I write a data migration that fills every row with its own unique value, built from its primary key (P1, P2, P3). Only after every row has a value do I change the field to null=False and unique=True.

So the constraint is applied after the data is ready, which makes the change safe and keeps the existing data intact.
